# “Gap Filling” for missing remote sensing observation

# Multi year remote sensing data

# “Gap Filling” for missing remote sensing observation

- Longitudinal remote sensing data are collected for studying various climate ecosystem phenomenon
- Often a lot of observations are missing due to various reasons
  - Cloud Cover
  - Aerosol Content
  - Change of instrument
  - Fire
  - Snow
- Geoscientists would love to fill those gaps for applying “standard statistical techniques.”

# Properties of remotely sensed ecosystem data

# Background and Context

## Model for independent curves

$$Y_i(t) = \sum_{k=1}^K \gamma_{ik} \phi_k(t) + \varepsilon_i(t)$$

where eigen-scores  $\gamma_{ik}$  are independent across  $i$ .

- However, in real world, many applications have correlated  $Y_i(t)$  across  $i$ .
  - ❖ example: spatial-temporal data, online auction data, time course gene expression data.
- Most existing work treat them as i.i.d.
- Asymptotic property holds for mild correlation.

# Previous Research

- Yao, Muller and Wang 2004 outlined the **moment based** methods to estimate covariance surface and eigenstructure of the random process assuming i.i.d. curves.
  - Also suggested reconstructing curve trajectories (“gap filling”) using expected principal component scores.

Question: How to estimate eigenstructure and reconstructing trajectories assuming correlated curves?

# Concurrent Research

- “Reduced Rank Mixed Effects Models for Spatially Correlated Hierarchical Functional Data” JASA 2010, Zhou et al.
  - Mentioned by Maurice Berk during his multilevel talk.
- Principal components analysis for sparsely observed correlated functional data using a kernel smoothing approach, Electron. J. Statist. Volume 5 (2011). Paul and Peng
- Some that I have missed ...

# Our Model for correlate data

## 2. Our Model:

$$Y_i(t) = \sum_{k=1}^K \gamma_{ik} \phi_k(t) + \varepsilon_i(t)$$

where

$$\text{cov}(\gamma_{ip}, \gamma_{jq}) = \begin{cases} 0, & p \neq q \\ \rho^{|i-j|} \lambda_k, & p = q = k \end{cases}$$

**more general model:**

$$\text{cov}(\gamma_{ip}, \gamma_{jq}) = \begin{cases} 0, & p \neq q \\ \text{matern}(d(i, j), \alpha_k, \beta_k) \lambda_k, & p = q = k \end{cases}$$

**Goal: estimating**  $\rho$  or more generally  $\alpha_k$  and  $\beta_k$

# Estimation of Parameters

## Moment Based Method

- local linear smoothing of the covariance surface  $\Sigma_0$  and
- lag-d cross-covariance surface  $\Sigma_d$  where  $d = 1, 2, \dots, D$ ,
- take ratios of eigenvalues as covariance estimates and fit matern or other parametric models.

## Likelihood based method

- Marginal likelihood is hard to optimize.
- Turn to joint likelihood of  $Y$  and treat as random effects.
- Use EM(expectation maximization) to solve the optimal parameters  $\rho, \alpha_k$  and  $\beta_k$

# Moment based method

- Covariance Model

$$\begin{aligned}\text{cov}(Y_i, Y_j) &= \Phi \text{cov}(\gamma_i, \gamma_j) \Phi' + \sigma^2 \mathbf{I} \\ &= \Phi \text{diag}(\text{cov}(\gamma_{i1}, \gamma_{j1}), \text{cov}(\gamma_{i2}, \gamma_{j2}), \dots, \text{cov}(\gamma_{iK}, \gamma_{jK})) \Phi' + \sigma^2 \mathbf{I}\end{aligned}$$

- Smooth covariance to get estimate of  $\Sigma_0 = \text{cov}(Y_i, Y_i)$ 
  - raw covariance  $G_i(T_{is}, T_{it}) = (Y_{is} - \mu(T_{is}))(Y_{it} - \mu(T_{it}))$
  - Smooth  $G_{ij}(T_{is}, T_{jt})$  using local linear smoother and get

# Moment based method

- Smooth lag-d covariance to get estimate of  $\sum_{d(i,j)} = \text{cov}(Y_i, Y_j)$   
where  $d(i, j) = d$ 
  - raw covariance  $G_{ij}(T_{is}, T_{jt}) = (Y_{is} - \mu(T_{is}))(Y_{jt} - \mu(T_{jt}))$
  - Smooth  $G_{ij}(T_{is}, T_{jt})$  using local linear smoother and get  $\hat{\sum}_{d(i,j)}$

# Moment based method

# Moment based method

How to use the lagged covariance surfaces

Calculate Eigenvalue ratio

eigenvalues of  $\Sigma_0$ :  $\pi_{0,k}, k = 1, 2, \dots, K$

eigenvalues of  $\Sigma_d$ :  $\pi_{d,k}, k = 1, 2, \dots, K$

For given  $k$ , we have  $\text{cor}_d(\gamma_{ik}, \gamma_{jk}) = \frac{\pi_{d,k}}{\pi_{0,k}}$  for  $d = 1, 2, \dots, D$

These  $\frac{\pi_{d,k}}{\pi_{0,k}}$  can be used to fit model parameters

# Simulation Results for moment based method

## Simulation scheme

- 3 eigenfunctions, 100 curves, 10 time points.
- AR(1) type spatial correlation(parameter is  $\rho$  )  
=0.2, 0.4, 0.6, 0.8.
- noise standard deviation  $\sigma = 0.05, 0.2, 0.5, 1.$
- Results for estimation of  $\rho$  eigenfunction 1 to 3 with moment based method

# Simulation Results: Ratio of first eigen values

rho.ind = 0.2, sigma sd = 0.05, eigenf 1 with lag = 1

$\rho_{\text{ind}} = 0.8$ ,  $\sigma \text{sd} = 1$ , eigenf 3 with lag = 16

# Likelihood Method

- Spatial correlation introduced through random effects
- Random effects are zero mean and satisfy the following

$$\text{cov}(\gamma_{ip}, \gamma_{jq}) = \begin{cases} 0, & p \neq q \\ \rho^{|i-j|} \lambda_k, & p = q = k \end{cases}$$

Then

$$\text{cov}(\tilde{\gamma}) = \begin{pmatrix} 1 & \rho & \rho^2 & \dots & \rho^{n-1} \\ \rho & 1 & \rho & \dots & \rho^{n-2} \\ \rho^2 & \rho & 1 & \dots & \rho^{n-3} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \rho^{n-1} & \rho^{n-2} & \rho^{n-3} & \dots & 1 \end{pmatrix} \otimes \Lambda$$

where

$$\Lambda = \begin{pmatrix} \lambda_1 & & \\ & \ddots & \\ & & \lambda_K \end{pmatrix}$$

# Likelihood Method

We express the eigenfunctions  $\{\phi_k(t)\}_{k=1}^K$  by basis expansion. Let  $\{\mathbf{B}_i\}_{i=1}^n$  be the evaluation matrix of basis and  $\Theta$  be the coefficient matrix of  $\{\phi_k(t)\}_{k=1}^K$  on basis functions. Then  $\Phi_i = \mathbf{B}_i \Theta$ . Hence, the full model is expressed as

$$\begin{aligned} \begin{pmatrix} \mathbf{Y}_1 \\ \vdots \\ \mathbf{Y}_n \end{pmatrix} &= \begin{pmatrix} \mathbf{B}_1 \Theta & & \\ & \ddots & \\ & & \mathbf{B}_n \Theta \end{pmatrix} \begin{pmatrix} \gamma_1 \\ \vdots \\ \gamma_n \end{pmatrix} + \begin{pmatrix} \epsilon_1 \\ \vdots \\ \epsilon_n \end{pmatrix} \\ &= \begin{pmatrix} \mathbf{B}_1 & & \\ & \ddots & \\ & & \mathbf{B}_n \end{pmatrix} \begin{pmatrix} \Theta & & \\ & \ddots & \\ & & \Theta \end{pmatrix} \begin{pmatrix} \gamma_1 \\ \vdots \\ \gamma_n \end{pmatrix} + \begin{pmatrix} \epsilon_1 \\ \vdots \\ \epsilon_n \end{pmatrix} \end{aligned}$$

where

- $\mathbf{Y}_i \rightarrow n_i \times 1$  vector of observed values for curve  $i$ .
- $\epsilon_i \rightarrow n_i \times 1$  vector of measurement errors for curve  $i$ .
- $\Phi_i \rightarrow n_i \times K$  matrix of eigenfunction evaluation on curve  $i$ .
- $\gamma_i \rightarrow K \times 1$  vector of random effects of curve  $i$
- $\mathbf{B}_i \rightarrow n_i \times P$  matrix of  $P$  basis functions evaluation.
- $\Theta \rightarrow P \times K$  matrix of coefficient matrix of  $K$  eigenfunctions on  $P$  basis functions.

The compact format becomes,

$$\tilde{\mathbf{Y}} = \tilde{\mathbf{B}} \tilde{\Theta} \tilde{\gamma} + \tilde{\epsilon}$$

# Likelihood Steps

Model:

$$\tilde{\mathbf{Y}} \sim \mathcal{N}(\mathbf{0}, \tilde{\mathbf{B}}\tilde{\Theta}\Gamma\tilde{\Theta}'\tilde{\mathbf{B}}' + \sigma^2\mathbf{I})$$

Marginal Likelihood

$$L(\tilde{\mathbf{Y}}) = (2\pi)^{-N/2} |\tilde{\mathbf{B}}\tilde{\Theta}\Gamma\tilde{\Theta}'\tilde{\mathbf{B}}' + \sigma^2\mathbf{I}|^{-1/2} \exp\left(-\frac{1}{2}\tilde{\mathbf{Y}}'(\tilde{\mathbf{B}}\tilde{\Theta}\Gamma\tilde{\Theta}'\tilde{\mathbf{B}}' + \sigma^2\mathbf{I})^{-1}\tilde{\mathbf{Y}}\right)$$

- Direct maximizing of this likelihood over  $\rho, \sigma^2, \Lambda$  and  $\Theta$  is a difficult non-convex optimization problem.
- Solution: EM procedure by treating random effects as missing data and focus on the joint log likelihood

Joint log likelihood

$$\begin{aligned} \mathcal{L}(\tilde{\mathbf{Y}}, \tilde{\gamma}) &= C - N \log \sigma - \frac{1}{2\sigma^2} \sum_{i=1}^n (\mathbf{Y}_i - \mathbf{B}_i\Theta\gamma_i)'(\mathbf{Y}_i - \mathbf{B}_i\Theta\gamma_i) \\ &\quad - \frac{1}{2} \left( K \log D(\rho) + n \sum_{k=1}^K \log \lambda_k + \sum_{i=1}^n \sum_{j=1}^n \sum_{k=1}^K g_{ij}(\rho) \lambda_k^{-1} \gamma_{ik} \gamma_{jk} \right) \end{aligned}$$

# EM Step

## E-Step:

It is easy to show that  $\mathbb{E}(\mathcal{L}(\mathbf{Y}, \tilde{\gamma})|\mathbf{Y}, \Delta)$  depends on  $\gamma_i$  only through  $\{\widehat{\gamma}_i = \mathbb{E}(\gamma_i|\mathbf{Y}, \Delta)\}_{i=1}^n$ ,  $\{\widehat{\gamma}_{ik}\widehat{\gamma}_{jk} = \mathbb{E}(\gamma_{ik}\gamma_{jk}|\tilde{\mathbf{Y}}, \Delta)\}_{k=1, i \neq j=1}^{K, n}$  and  $\{\widehat{\gamma}_i\widehat{\gamma}_i' = \mathbb{E}(\gamma_i\gamma_i'|\tilde{\mathbf{Y}}, \Delta)\}_{i=1}^n$ . Note that for each  $i$ ,  $\widehat{\gamma}_i\widehat{\gamma}_i' = \widehat{\gamma}_i\widehat{\gamma}_i' + \mathbb{V}(\gamma_i|\tilde{\mathbf{Y}}, \Delta)$

## M-Step

M-step is to maximize  $\mathbb{E}(\mathcal{L}(\tilde{\mathbf{Y}}, \tilde{\gamma})|\tilde{\mathbf{Y}}, \Delta)$  over  $\Lambda$ ,  $\Theta$ ,  $\sigma^2$  and  $\rho$ .

- Note that  $\Lambda$  and  $\rho$  are separated from  $\Theta$  and  $\sigma^2$
- optimization over these parameters one at a time and do it iteratively.

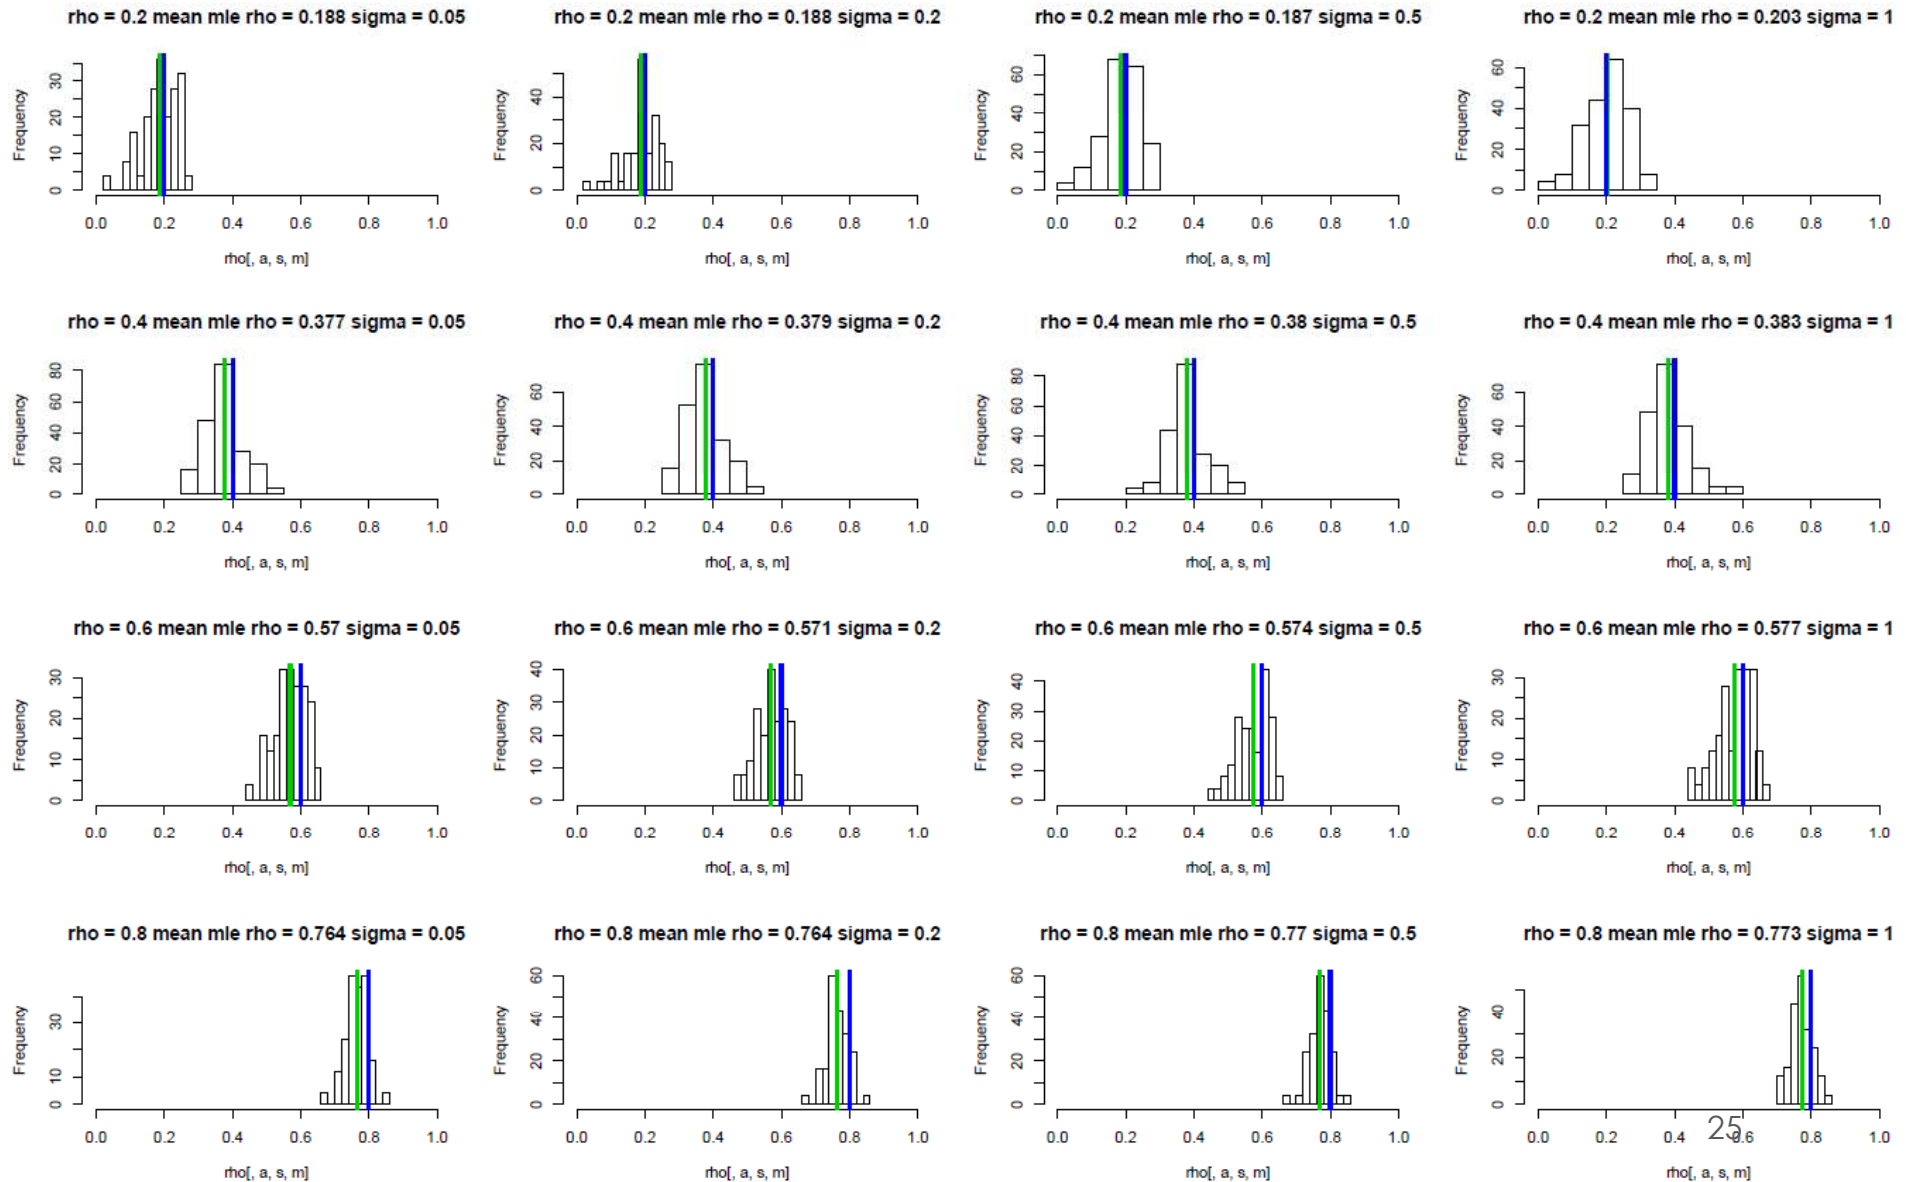

# Simulation Results for moment based method

## Simulation scheme

- 3 eigenfunctions, 100 curves, 10 time points.
- AR(1) type spatial correlation(parameter is  $\rho$ ) =0.2, 0.4, 0.6, 0.8.
- noise standard deviation  $\sigma = 0.05, 0.2, 0.5, 1$ .
- Results for estimation of  $\rho$  eigenfunction 1 to 3 with moment based method

# EM estimates of correlation parameter

# Reconstruction Results

- Given the estimate of spatial correlation structure, we can compute the expected principal component scores  $\gamma_{ik}$

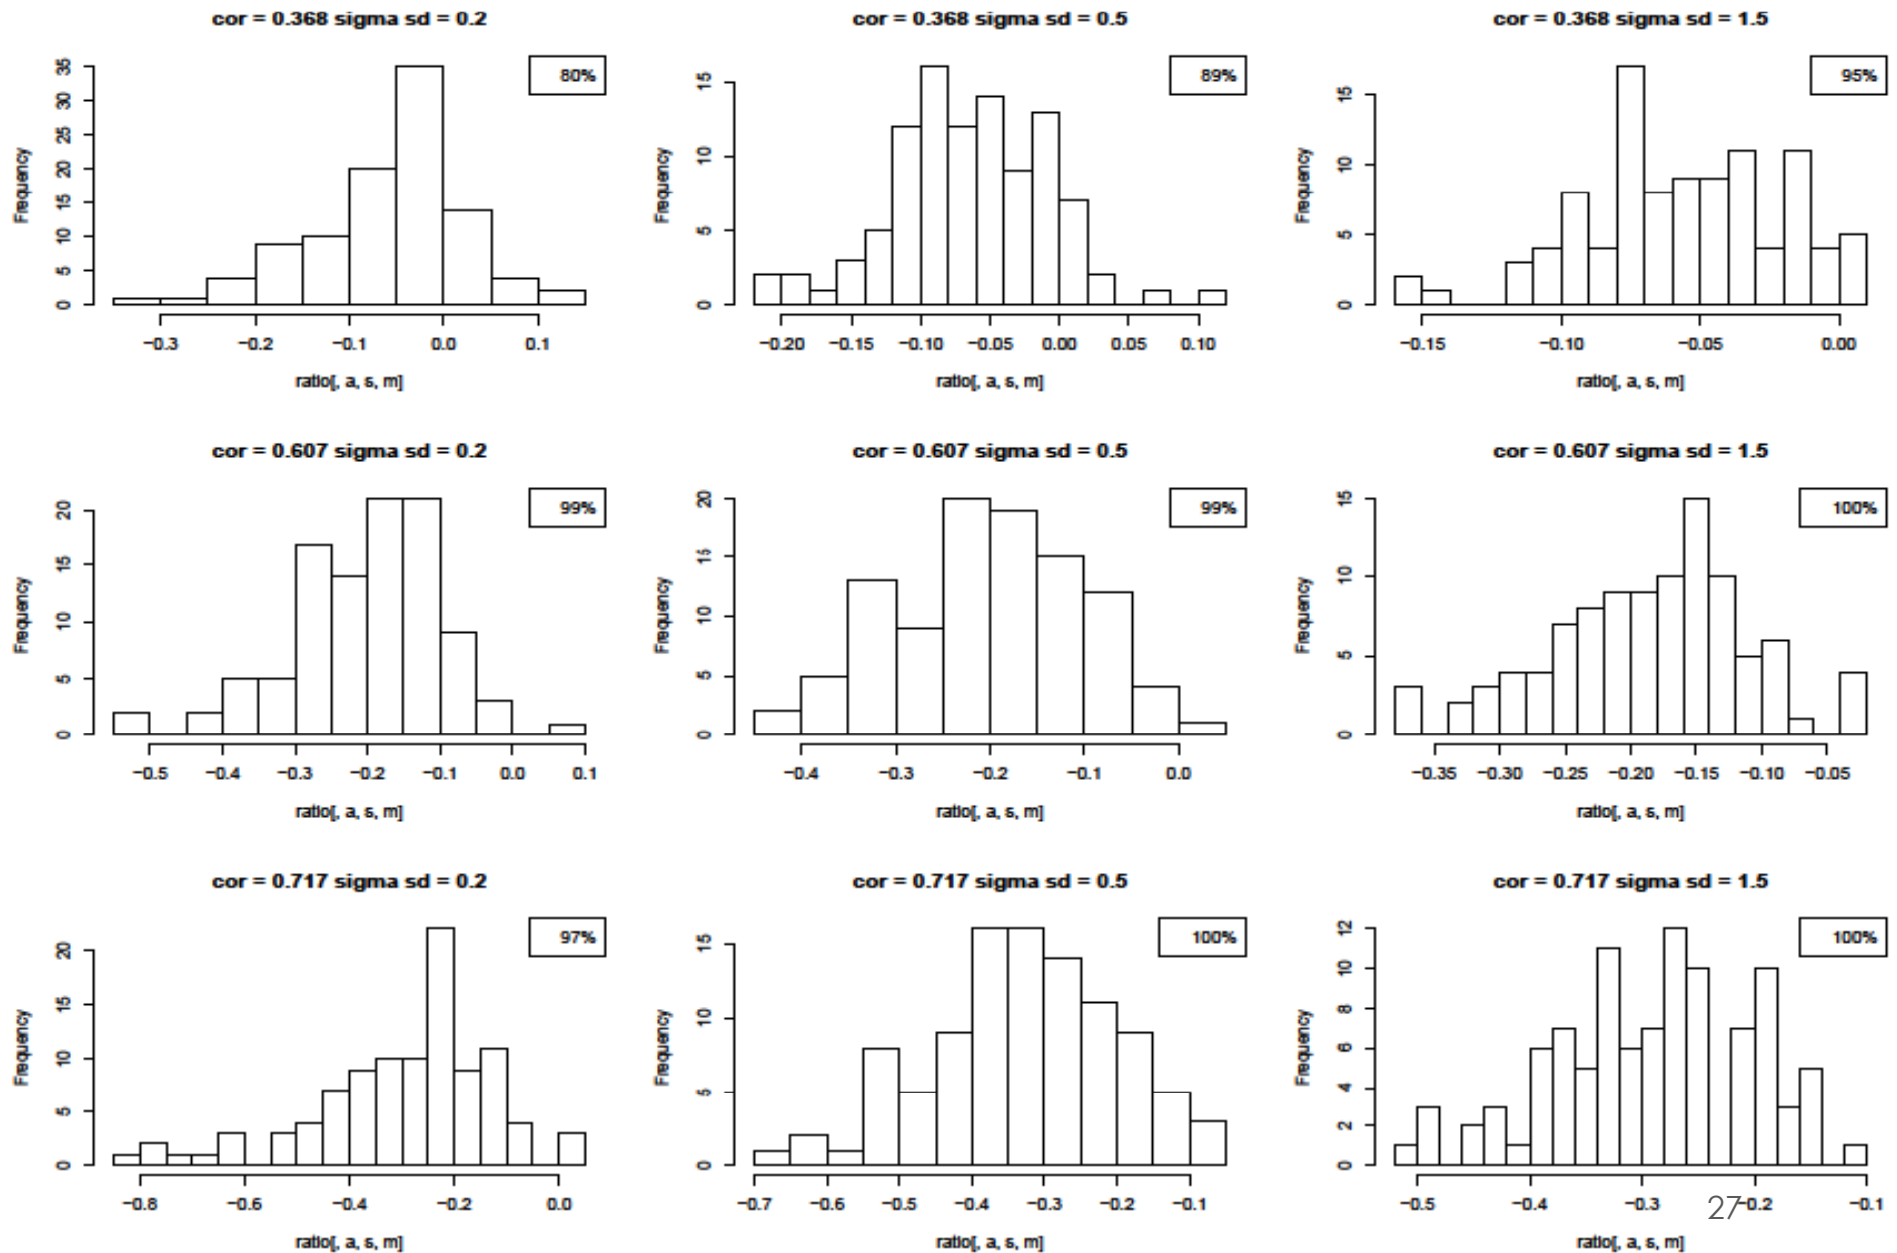

$$\hat{\gamma}_{ik} = E(\gamma_{ik} | Y_1, Y_2, \dots, Y_N)$$

- In the i.i.d curve case, the information set only include curve i,

$$\hat{\gamma}_{ik} = E(\gamma_{ik} | Y_i)$$

- For AR(1) correlated curves, curves were reconstructed using using  $\hat{\gamma}_{ik}$  and  $\hat{\gamma}_{ik}$
- Performance measured by sum of squared errors over all curves.
- Negative log ratio suggest better performance

# Histogram of log ratio of squared error

# Future Work

## Consistency

- For moment based estimates

## Strict geometric constraints for solving the EM steps.

- Hypothesize better convergence results from this approach.
- Following Peng and Paul's , 2009 paper on "A geometric approach to maximum likelihood estimation of the functional principal components from sparse longitudinal data"

## Software:

- SPACE (Spatial Principal Analysis by Conditional Estimation)
- First version with limited spatial correlation choices.
- Follow up versions with more general spatial correlation.
